

# TORONTO BUS DELAYS

ST3082 Project II  
Advanced Data Analysis

Group 04

s14853 – Pramudi Rajamanthri  
s15030 – Vidura Chathuranga  
s15091 – Chalani Wijamunige

## **Abstract**

This report aims to outline the findings of the exploratory data analysis which was carried out based on the Toronto bus delays 2022 data set obtained from the open-source data site, Kaggle. Furthermore, an advanced analysis was carried out on identifying the frontline reasons for Toronto bus delays along with their inter relationships and fitting a suitable model to predict the delay time of buses with high accuracy.

## **1. Introduction**

In Toronto, buses play a major role in public transportation. As per records in 2021, TTC bus system has 192 bus routes in operation including 28 night bus routes carrying over 264 million riders over 6686 kilometers of routes with buses travelling 143 million kilometers in the year. The system had a ridership of about 8,74,300 per weekday by the end of first 6 months of 2022. Bus routes extend throughout the city and are integrated with the subway system and the streetcar system with free transfers among the 3 systems. In the recent past years, TTC is constantly being complained on the delays of the bus system despite of having a wide network. Numerous research studies have been done on the factors leading to these delays in order to fix this issue with the guidance of the professionals, since the primary objective of transportation efficiency is directly affected from these delays in the bus system. With the dataset in hand, an analysis can be performed to find the factors that have the most influence on bus delays in Toronto and a model can be built in order to predict the delay time in minutes accurately for the ease and the awareness of the riders.

## **2. Description of the Question**

It is important and timely to address the issue in drop of efficiency in the Toronto bus system due to delays, in order to fix the problematic spots in the bus network, as it is directly connected with the day today life activities of millions of people. Hence, identifying and understanding the main factors resulting this issue is essential in setting the path to predict the delay time in minutes out of the visible causes such as route types, incidents causing delays, week of the day etc, to make the passenger lives easy by being aware of the possible amount of delay times.

## **3. Description of the data set**

The Toronto bus delays 2022 dataset contains 27351 records and 10 variables, including Delay time as the response variable.

Variable Name	Description	Variable Type
Date	Date of the delay incident	Qualitative
Route	Route number which the incident happened	Qualitative
Time	Time of the day which the incident happened	Quantitative
Day	Day of the week which the incident happened	Qualitative
Location	Location in Toronto which the delay incident happened	Qualitative
Incident	The incident which caused the delay	Qualitative
Min.Delay	Amount of time which the bus got delayed	Quantitative
Min.Gap	Time gap in minutes with the next bus scheduled	Quantitative
Direction	Direction of the route which the particular bus travels	Qualitative
Vehicle	Vehicle number of the bus	Qualitative

*Table 3.1*

## **4. Pre-processing**

Toronto bus delay dataset contains data under 10 variables where 7 are categorical and 3 are numerical. In the dataset, 154 duplicated entries were discovered and those were removed. Then it was found that there are 164 missing data records in the *Route* variable and 5529 missing records in the “*Direction*” variable. Afterwards, all the records having 0 as the *Min.Delay* and *Min.Gap* were removed from the dataset as only the buses which got delayed are being considered in the analysis. By doing so, the count of missing values of *Route* and *Direction* variables got reduced to 26 and 4987 respectively with a total of 25898 records.

### **4.1 Feature Engineering**

A separate “Month” variable was created by extracting the months in the “Date” variable. Distinct values in the “*Direction*” column were identified and entries with error values discovered in that variable were filtered out. Considering the “*Route*” variable, routes labelled in text form were replaced by a random number for the ease of cleaning process.

1.Regular and Limited Service Routes	7 – 189 series	Weekdays – 6am-1am Weekends - 8am-1am
2.Blue Night Routes	300 -399 series	Weekdays – 1am-6am Weekends - 1am-8am
3.Community Routes	400 – 499 series	Only in rush hours of weekdays Rush hours (According to TTC statistics) :- Morning – 6am- 10am Evening - 3pm- 7pm
4.Express Routes	900 – 999 series	Any time with in the 24 hours (according to requirements)

*Table 4.1*

Based on the above details we got from the TTC official website, the new variable *Route\_New* was created by categorizing all the distinct routes in the “*Route*” variable into 5 categories (Blue Night Routes, Community Routes, Express Routes, Regular and limited service routes, Others) based on their route numbers. The “*Hour*” variable was introduced to the dataset by extracting the hours in the “*Time*” variable. The new variable *is\_Weekday* was formed by categorizing the days in the *Day* column into 2 categories (Weekday, Weekend). The *Incident\_New* variable was created by taking the distinct categories in the “*Incident*” column and combining 3 categories with lowest number of cases (Cleaning – Disinfection, Held By, Late

Entering Service) into one category (Others), and renaming the category “Road Blocked – NON-TTC Collision” into “Road Blocked”. The *Vehicle* variable was removed from the dataset as it acts as an identifying variable and it causes no effect for the delay analysis.

Furthermore, by referring to the website of TTC bus system, the operating days and times of the bus routes were identified and the records which do not follow this day and time system under its corresponding bus route were filtered out as they are contradictory with the system data which left us with a total of 23853 records. Finally, the dataset was split into training and test data sets as 80% and 20% from the original data respectively for further analysis. Afterwards the variables with missing values of the training set were taken into consideration and we identified missing values in *Route*, *Route\_New* and *Direction* variables as 24, 24, 3528 respectively. As *Route* variable is not considered for further analysis while *Direction* variable leads to misinterpretations with imputing using the mode as all its categories have approximately equal number of data currently, we only imputed the *Route\_New* variable using the *Hour* and the *is\_Weekday* observations relevant to those records with data in Table 4.1.

## **5. Important Results of the Descriptive Analysis**

In the detailed descriptive analysis carried out previously, the behavior of the delay time was analyzed with several associative factors. Below are some important results obtained.

- When the delay time distribution was analyzed, a positively skewed distribution was observed along with 994 outliers. Hence, considering a transformation on the response would help to overcome the issues arising from the above.
- Most delay cases were reported in the regular and limited service routes( 7-189) as it functions from 6am-1am and 8am-1am on weekdays and weekends respectively .Furthermore the buses which travel towards North Toronto tend to report more delays.
- Weekdays record the most number of delay cases with in 6am-7pm particularly as those are the identified rush hours in weekdays according to the statistics of TTC. Mechanical problems and delays in operations due to the operators are the major reasons which were identified as the causes of the delays with in these identified time period.

*Figure 5.1*

- The time gap between the scheduled time of two buses shares a positive linear relationship with the delay time, along with a considerably higher correlation of 0.96.

*Figure 5.2*

- Partial least squares regression(PLSR),also resulted a dominant VIP score for Min.Gap which confirmed the identified linear relationship between Min.Gap and Min.Delays . Moreover, 35 outliers were identified via PLSR.

Figure 5.3

- Cluster analysis confirmed the non-existence of clearly distinct clusters where it resulted average silhouette distances less than 0.1 for the considered k values in the range of 2:8 where the highest value was 0.0894 under k=3.

Figure 5.4

Figure 5.5

- Apart from the strong linear correlation of 0.96 identified between *Min.Gap* and *Min.Delay*, strong associations were identified among the *Min.Gap* and categorical predictors such as *Route\_New* , *Incident\_New* and *Hour* etc through the Kruskal Wallis results where there were strong associations among the categorical predictors identified through chi squared test results also.

## 6. Important Results of the Advanced Analysis

The predictive models analyzed throughout this analysis are derived with the assumption that the *Min.Delay* variable is of continuous data. Accordingly, with regard to the final result of the descriptive analysis mentioned above, fitting a multiple linear regression model is not appropriate due to the presence of associations identified among the predictor variables. Hence, regularization techniques were used to reduce the variance of the coefficient estimates. Table 6.1 below is a model performance evaluation done on the predicted delays and that of actual counts using the Root Mean Squared Error (RMSE) metric with 10- fold cross validation.

Model	Training RMSE	Test RMSE	Test MAPE
Ridge	4.919888	7.255654	15.89%
Lasso	4.93747	7.271554	16.16%
Elastic Net	4.797923	7.509318	22.75%

Table 6.1

Comparing the table values of the Test RMSE for the three models, clearly the ridge model reports the lowest, furthermore it has the lowest difference between the training and test RMSE values depicting to have the maximum minimization of the issue of overfitting. Hence, selecting a comprehensive model by considering the above three models might be fair enough.

But, obtaining 15.89% MAPE value suggests a considerably less prediction accuracy relevant to the ridge model.

Hence, to improve the model accuracy regarding the MAPE, more sophisticated but that can handle multiple issues simultaneously were applied. Table 6.2 below are the results obtained using random forest and XGBoosting after hyper parameter tuning.

Model	With all the features				With the important features		
	Best Parameters	Training RMSE	Test RMSE	Test MAPE	Training RMSE	Test RMSE	Test MAPE
Random Forest	mtry=50 splitrule=variance min.node.size=5	3.595297	5.278197	9.18%	3.746567	6.524895	14.75%
XGBoost	nrounds=500 max_depth=2 eta=0.1 gamma=0.1 colsample_bytree=0.6 min_child_weight=1 subsample=0.5	2.799788	5.520246	9.57%	3.868539	6.530456	14.86%

Table 6.2

Note: the importance of features for the Random Forest and XGBoosting were decided by taking all the features that have scores greater than 100 and 0.1 respectively.

As depicted on Table 6.2, the results obtained when all the features were considered, both the techniques suggest that prediction accuracy has increased but comparatively the random forest model with all the features shows better results with both less Test RMSE and Test MAPE. Despite all that, Test MAPE values seem to have reduced compared to all the regression models applied in this case. Moreover, the random forest and xgboost models considering all the features reported training MAPE values of 7.56% and 5.58% respectively, approving the fact that random forest model with all the features is less overfitted. Even though, models with the important features were fitted, the prediction accuracy has decreased with considerably higher Test MAPE values. Table below shows the variable importance plots of the two models with all the features considered.

From both models we observe that the variable *Min.Gap* has resulted a dominant importance in predicting the delays, leaving majority of other variables negligible. This observation coincides with the result that we identified in the descriptive analysis where the scatterplot of *Min.Gap Vs Min.Delay* depicted a perfect positive linear relationship with a correlation coefficient of 0.96.

The response variable's discreteness and the possession of a positively skewed distribution indicates that using a transformation on the response might produce more accurate predictions. Therefore, log transformation is imposed on the response, *Min.Delay*.

	Response – Min.Delay	Response – Log(Min.Delay)
Skewness	5.192685	0.6769573
Kurtosis	37.93428	5.319729

Figure 6.3

Table 6.3 below is a model performance evaluation done on the predicted delays after transforming them back to the original scale and that of actual counts using the Root Mean Squared Error (RMSE) metric with 10-fold cross validation.

Model	Training RMSE	Test RMSE	Test MAPE
Ridge	30.85677	42.79989	35.59%
Lasso	25.99747	38.51643	25.42%
Elastic Net	33.03114	48.24348	35.75%

Table 6.3

Above results show that the log transformation has not been successful in fitting linear relationships between the response and predictors where the figure 6.4 confirms that the perfect positive linear relationship between Min.Delay and Min.Gap has become non-linear between ln(Min.Delay) and Min.Gap as it is identified as the most important predictor in this scenario. Hence we decided to shift to the random forest and xgboost methods from the regularization techniques in search of more accuracy.

Figure 6.4

.Table 6.4 below are the results obtained using random forest and XGBoosting after transforming them back to the original scale.

Model	With all the features				With the important features		
	Best Parameters	Training RMSE	Test RMSE	Test MAPE	Training RMSE	Test RMSE	Test MAPE
Random Forest	mtry=35 splitrule=variance min.node.size=5	4.571086	6.377511	13.49%	2.654157	6.973025	14.82%
XGBoost	nrounds=500 max_depth=2 eta=0.1 gamma=0.1 colsample_bytree=0.5 min_child_weight=1 subsample=0.6	3.172071	6.110895	11.97%	3.450382	6.312643	13.28%

Table 6.4

Note: the importance of features for the Random Forest and XGBoosting were decided by taking all the features that have scores greater than 0.1.

As depicted on Table 6.4, the results obtained when all the features were considered, both the techniques suggest that prediction accuracy is high in terms of both RMSEs and Test MAPE but lower comparatively to the results we obtained for the random forest model and XGBoost models considering the response in original scale. Even though, models with the important features have increased the accuracy in the training data, the prediction accuracy has decreased related to the test data with a considerable amount of overfitting and higher Test MAPE values. Figure 6.5 and Figure 6.6 depict the variable importance plots relevant to this scenario.

## 7. Issues Encountered and Proposed Solutions

- Presence of a large number of factor levels in a categorical variable would make the model very complicated therefore before fitting the models some of similar factor levels and some factor levels with very low representation were combined together with the intention of reducing the number of factor levels in a categorical variable
- The dataset which was used for the analysis comprised of categorical variables with many factor levels. In order to fit a model, these variables had to be replaced with dummy variables. As a result, the different factors were separated into many dummy variables, it caused difficulties in interpreting the model since each factor level for the same categorical variable had different levels of importance where some factors had extremely high feature importance while the factors had very low feature importance.
- When almost all the models didn't show vast differences in terms of training and test RMSEs, in order to identify which models are overfitted, we considered their training and test MAPEs particularly for the models with considerably less training and test RMSEs which paved the path to select the best model.

## 8. Discussion and Conclusions

- Even though our initial distribution of the response variable was highly skewed to the right, the models which were fitted under the regularization techniques Ridge, lasso and Elastic Net resulted fair enough RMSE values.
- It was evident that *Min.Gap* variable is dominant among all the variables in all the variable importance plots coinciding with the fact it shares a correlation of 0.96 with the response. Due to the above reason the results of the models with all the features and only the important features didn't result vast differences in terms of RMSE values.
- The results obtained in random forest model considering all the features showed the highest accuracy regarding the test RMSE and test MAPE values which are 5.278197 ,9.18% respectively. Moreover, the obtained training MAPE was reported to be 7.56% which approves the minimum overfitting of the model. The obtained results after log transformation relevant to the ensemble techniques also were fair enough but not better than the results obtained from the random forest model on the response variable.

- When all the models were compared, the Random Forest model applied on the original response considering all the features was identified as the best model which produces the most accurate predictions with less information loss. Figure 8.1 shows the partial dependency plot of Min.Gap which is the only numerical variable in the selected random forest model where it depicts the predicted delay time increases as the time gap increases in the model.

*Figure 8.1*
